Release mechanisms are distinguished by generation-time structure
release spread across cell age
release concentrated at an event
Continuous budding
many small releases while productive
g(a) = p S(a)
Pulsatile export
stock–export, ON/OFF, or self-exciting release
clustered but non-terminal
Recurrent batch release
boolean partial clear or reset dumps
X → X − B, possibly repeatedly
Absorbing BDC burst
one load-proportional terminal dump
g(a) = δK(a),
Stage structure modifies the age kernel
E1 → E2 → · · · → En → I
An eclipse chain delays and reshapes release; it can precede budding, pulsed export, or a burst, but does not by itself choose the release mechanism.
shared stage language only
HIV: contrast class, not BDC
multi-stage eclipse → short productive budding pulse
gHIV is not δK; there is no terminal load-proportional dump
